# Grand Unification in the Spectral Pati-Salam Model

- History of the meter: the spectral approach
- Fermions in spacetime and emerging bosons
- Noncommutative fine structure of spacetime
- Examples: electroweak model, Standard Model
- Beyond the Standard Model: Pati-Salam unification

Meter defined in 1791 as  $10^{-7}$  times one quarter of the meridian of the Earth.

Expedition in 1792: measuring the arc of the meridian between Barcelona-Duinkerken, at the beginning of the French revolution... <sup>a</sup>

<sup>a</sup>Adler (2002)

Meter made concrete by platinum bar "mètre-étalon", saved (from 1889) in Pavillon de Breteuil near Paris:

Practical objections mètre-étalon (natural variations):

• 1960: meter defined as a multiple of a transition wavelength in Krypton 86Kr:

• 1967: **second** = 9192631770 periods of a transition radiation between two hyperfine levels in Caesium-133.

 1983: Definition of the meter as the distance that light travels in 1/299792458 second...

So, measuring distances by looking at spectra

### A fermion in a spacetime background

Minimal ingredients to describe a free fermion:

• coordinates on spacetime *M*:

$$x_{\mu} \cdot x_{\nu}(p) = x_{\mu}(p)x_{\nu}(p),$$
 etc.,

with  $\mu, \nu = 1, ..., 4$ .

propagation, described by Dirac operator ∂<sub>M</sub> = iγ<sup>μ</sup>∂<sub>μ</sub>, acting on wavefunctions ψ:

$$S[\psi] = \int \overline{\psi} \partial_M \psi \qquad \rightsquigarrow \text{EOM: } \partial_M \psi = 0.$$

 This combination of coordinate algebra and operators is central to the spectral, or noncommutative approach [C 1994].

# **Emerging bosons**

Our fermionic starting point induces a bosonic theory:

• "Inner fluctuations" by the coordinates [C 1996]:

$$\partial_M \rightsquigarrow \partial_M + \sum_j a_j [\partial_M, a'_j]$$

for functions  $a_j, a'_j$  depending on the coordinates  $x_{\mu}$ .

• Then, by the chain rule:

$$\sum_{j} a_{j}[\partial_{M}, a_{j}'] = A^{\nu} \gamma^{\mu} (\partial_{\mu} x^{\nu}) = A^{\mu} \gamma_{\mu}$$

where  $A^{\mu}$  is the electromagnetic 4-potential describing the photon.

Moreover, it is possible to derive a bosonic action from the (Euclidean) Dirac operator via the spectral action [CC 1996]:

$$\mathsf{Trace}\, e^{-\partial_M^2/\Lambda^2} \sim c_4 \Lambda^4 \mathsf{Vol}(M) + c_2 \Lambda^2 \int R \sqrt{g} + c_0 \int (\partial_{[\mu} A_{\nu]})^2 + \cdots$$

for some coefficients  $c_4, c_2, \ldots$ 

We recognize

- The Einstein-Hilbert action  $\int R\sqrt{g}$  for (Euclidean) gravity
- The Lagrangian  $\int (\partial_{[\mu} A_{
  u]})^2$  for the electromagnetic field

 $\bullet \land \land \land \land \bullet \bullet$ 

Replace spacetime by spacetime  $\times$  noncommutative space:  $M \times F$ 

- F is considered as internal space (Kaluza-Klein like)
- F is described by noncommutative matrices, that play the role of coordinates, just as spacetime is described by x<sub>μ</sub>(p).
- 'Propagation' of particles in F is described by a 'Dirac operator' 
   *φ*<sub>F</sub> which is actually simply a hermitian matrix.

Note that the spectral approach is now the only way to describe the geometry of F.

#### Example: electroweak theory

Coordinates on F are elements in  $\mathbb{C} \oplus \mathbb{H}$ 

- A complex number z
- A quaternion  $q = q_0 + iq_k\sigma^k$ ; in terms of Pauli matrices:

$$\sigma^{1} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma^{2} = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}, \quad \sigma^{3} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

It describes a two-point space, with internal structure:

Gauge group is given by unitaries:  $U(1) \times SU(2)$ .

'Dirac operator'

$$\phi_F = \begin{pmatrix} 0 & \overline{c} & 0 \\ c & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

• "Inner fluctuations" can be defined as before but now yield:

#### Almost-commutative spacetimes

We combine this mild (matrix) noncommutativity with spacetime:

• coordinates of the almost-commutative spacetime  $M \times F$ :

$$\hat{x}^\mu(p)=(z^\mu(p),q^\mu(p))$$

as elements in  $\mathbb{C} \oplus \mathbb{H}$  (for each  $\mu$  and each point p of M)

The combined Dirac operator becomes

$$\partial_{M\times F} = \partial_M + \gamma_5 \partial_F$$

Note that  $\partial^2_{M \times F} = \partial^2_M + \partial^2_F$ , which will be useful later on.

Walter van Suijlekom

### Inner fluctuations on $M \times F$

So, we describe  $M \times F$  by:

$$\hat{x}^{\mu}=(z^{\mu},q^{\mu})$$
 ;  $\partial_{M imes F}=\partial_{M}+\gamma_{5}\partial_{F}$ 

As before, we consider inner fluctuations of  $\hat{p}_{M \times F}$  by  $\hat{x}^{\mu}(p)$ :

- The inner fluctuations of  $\partial_F$  become scalar fields  $\phi_1, \phi_2$ .
- The inner fluctuations of  $\partial_M$  become matrix-valued:

$$\sum_{j} a_{j}[\partial_{M}, a_{j}'] = a_{\nu} \gamma^{\mu} (\partial_{\mu} \hat{x}^{\nu}) =: \partial_{M} + A_{\mu} \gamma^{\mu}$$

with  $A_{\mu}$  taking values in  $\mathbb{C} \oplus \mathbb{H}$ :

$$A_{\mu} = egin{pmatrix} B_{\mu} & 0 & 0 \ 0 & W^3_{\mu} & W^+_{\mu} \ 0 & W^-_{\mu} & -W^3_{\mu} \end{pmatrix}$$

corresponding to hypercharge and the W-bosons.

Walter van Suijlekom

#### Action functional: electroweak theory

Use  $\partial^2_{M \times F} = \partial^2_M + \partial^2_F$  to compute the spectral action

$$\begin{aligned} \text{Trace } e^{-\hat{\rho}_{M\times F}^{2}/\Lambda^{2}} &= \text{Trace } e^{-\hat{\rho}_{M}^{2}/\Lambda^{2}} \left(1 - \frac{\hat{\rho}_{F}^{2}}{\Lambda^{2}} + \frac{1}{2}\frac{\hat{\rho}_{F}^{4}}{\Lambda^{4}} - \cdots\right) \\ &\sim \left(c_{4}\Lambda^{4}\text{Vol}(M) + c_{2}\Lambda^{2}\int R\sqrt{g} + c_{0}\int F_{\mu\nu}F^{\mu\nu}\right) \left(1 - \frac{|\phi|^{2}}{\Lambda^{2}} + \frac{|\phi|^{4}}{2\Lambda^{4}}\right) + \end{aligned}$$

We now recognize in terms of the field-strength  $F_{\mu\nu}$  for  $A_{\mu}$ :

- The Yang–Mills term  $F_{\mu\nu}F^{\mu\nu}$ for hypercharge and W-boson
- The Higgs potential  $-c_4\Lambda^2|\phi|^2 + \frac{1}{2}c_4|\phi|^4$

#### Standard Model as an almost-commutative spacetime

Describe  $M \times F_{SM}$  by [CCM 2007]

- Coordinates: x̂<sup>µ</sup>(p) ∈ C ⊕ ℍ ⊕ M<sub>3</sub>(C) (with unimodular unitaries U(1)<sub>Y</sub> × SU(2)<sub>L</sub> × SU(3)).
- Dirac operator  $\partial_{M \times F} = \partial_M + \gamma_5 \partial_F$  where

$$\partial_F = \begin{pmatrix} S & T^* \\ T & \overline{S} \end{pmatrix}$$

is a 96  $\times$  96-dimensional hermitian matrix where 96 is:

# The Dirac operator on $F_{SM}$

$$\partial F = \begin{pmatrix} S & T^* \\ T & \overline{S} \end{pmatrix}$$

• The operator S is given by

$$S_{I} := \begin{pmatrix} 0 & 0 & Y_{\nu} & 0 \\ 0 & 0 & 0 & Y_{e} \\ Y_{\nu}^{*} & 0 & 0 & 0 \\ 0 & Y_{e}^{*} & 0 & 0 \end{pmatrix}, \quad S_{q} \otimes 1_{3} = \begin{pmatrix} 0 & 0 & Y_{u} & 0 \\ 0 & 0 & 0 & Y_{d} \\ Y_{u}^{*} & 0 & 0 & 0 \\ 0 & Y_{d}^{*} & 0 & 0 \end{pmatrix} \otimes 1_{3},$$

where  $Y_{\nu}$ ,  $Y_e$ ,  $Y_u$  and  $Y_d$  are  $3 \times 3$  mass matrices acting on the three generations.

 The symmetric operator T only acts on the right-handed (anti)neutrinos, Tν<sub>R</sub> = Y<sub>R</sub>ν<sub>R</sub> for a 3 × 3 symmetric Majorana mass matrix Y<sub>R</sub>, and Tf = 0 for all other fermions f ≠ ν<sub>R</sub>.

### Inner fluctuations

Just as before, we find

• Inner fluctuations of  $\partial_M$  give a matrix

$$A_{\mu} = \begin{pmatrix} B_{\mu} & 0 & 0 & 0 \\ 0 & W_{\mu}^{3} & W_{\mu}^{+} & 0 \\ 0 & W_{\mu}^{-} & -W_{\mu}^{3} & 0 \\ 0 & 0 & 0 & (G_{\mu}^{a}) \end{pmatrix}$$

corresponding to hypercharge, weak and strong interaction.

• Inner fluctuations of  $\mathcal{D}_F$  give

$$\begin{pmatrix} Y_{\nu} & 0\\ 0 & Y_{e} \end{pmatrix} \rightsquigarrow \begin{pmatrix} Y_{\nu}\phi_{1} & -Y_{e}\overline{\phi}_{2}\\ Y_{\nu}\phi_{2} & Y_{e}\overline{\phi}_{1} \end{pmatrix}$$

corresponding to SM-Higgs field. Similarly for  $Y_u$ ,  $Y_d$ .

### Dynamics and interactions

If we reconsider the spectral action:

$$\mathsf{Trace}\, e^{-\hat{\rho}_{M\times F}^2/\Lambda^2} \sim \left(c_4 \Lambda^4 \mathsf{Vol}(M) + c_0 \int \mathcal{F}_{\mu\nu} \mathcal{F}^{\mu\nu}\right) \left(1 - \frac{|\phi|^2}{\Lambda^2} + \frac{|\phi|^4}{2\Lambda^4}\right) +$$

we observe [CCM 2007]:

 The coupling constants of hypercharge, weak and strong interaction are expressed in terms of the single constant c<sub>0</sub> which implies

$$g_3^2 = g_2^2 = \frac{5}{3}g_1^2$$

In other words, there should be grand unification.

• Moreover, the quartic Higgs coupling  $\lambda$  is related via

$$\lambda pprox 24 rac{3+
ho^4}{(3+
ho^2)^2} g_2^2; \qquad 
ho = rac{m_
u}{m_{
m top}}$$

# Phenomenology of the noncommutative Standard Model

This can be used to derive predictions as follows:

- Interpret the spectral action as an effective field theory at  $\Lambda_{GUT}\approx 10^{13}-10^{16}$  GeV.
- Run the quartic coupling constant  $\lambda$  to SM-energies to predict

### Three problems

- This prediction is falsified by the measured value.
- In the Standard Model there is not the presumed grand unification.
- S There is a problem with the low value of m<sub>h</sub>, making the Higgs vacuum un/metastable [Elias-Miro et al. 2011].

#### Beyond the SM with noncommutative geometry A solution to the above three problems?

• The matrix coordinates of the Standard Model arise naturally as a restriction of the following coordinates

 $\hat{x}^{\mu}(p) = ig(q^{\mu}_{R}(p),q^{\mu}_{L}(p),m^{\mu}(p)ig) \in \mathbb{H}_{R} \oplus \mathbb{H}_{L} \oplus M_{4}(\mathbb{C})$ 

corresponding to a Pati-Salam unification:

 $U(1)_Y \times SU(2)_L \times SU(3) \rightarrow SU(2)_R \times SU(2)_L \times SU(4)$ 

• The 96 fermionic degrees of freedom are structured as

$$\begin{pmatrix} \nu_{R} & u_{iR} & \nu_{L} & u_{iL} \\ e_{R} & d_{iR} & e_{L} & d_{iL} \end{pmatrix}$$
  $(i = 1, 2, 3)$ 

• Again the finite Dirac operator is a 96 × 96-dimensional matrix (details in [CCS 2013]).

• Inner fluctuations of  $\partial_M$  now give three gauge bosons:

$$W^{\mu}_{R}, \qquad W^{\mu}_{L}, \qquad V^{\mu}$$

corresponding to  $SU(2)_R \times SU(2)_L \times SU(4)$ .

 For the inner fluctuations of *∂<sub>F</sub>* we distinguish two cases, depending on the initial form of *∂<sub>F</sub>*:

I The Standard Model 
$$\partial_F = \begin{pmatrix} S & T^* \\ T & \overline{S} \end{pmatrix}$$

II A more general  $\partial_F$  with zero  $\overline{f}_L - f_L$ -interactions.

#### Scalar sector of the spectral Pati-Salam model

Case I For a SM  $\partial_F$ , the resulting scalar fields are composite fields, expressed in scalar fields whose representations are:

	$SU(2)_R$	$SU(2)_L$	SU(4)
$\phi^b_a$	2	2	1
$\Delta_{al}$	2	1	4
$\Sigma'_J$	1	1	15

Case II For a more general finite Dirac operator, we have fundamental scalar fields:

particle	$SU(2)_R$	$SU(2)_L$	SU(4)
$\Sigma^{bJ}_{aJ}$	2	2	1 + 15
ц .∫	3	1	10
''àlḃJ \	1	1	6

As for the Standard Model, we can compute the spectral action which describes the usual Pati–Salam model with

unification of the gauge couplings

$$g_R = g_L = g$$
.

• A rather involved, fixed scalar potential, still subject to further study

## Phenomenology of the spectral Pati–Salam model

However, independently from the spectral action, we can analyze the running at one loop of the gauge couplings [CCS 2015]:

- We run the Standard Model gauge couplings up to a presumed PS  $\rightarrow$  SM symmetry breaking scale  $m_R$
- We take their values as boundary conditions to the Pati-Salam gauge couplings g<sub>R</sub>, g<sub>L</sub>, g at this scale via

$$\frac{1}{g_1^2} = \frac{2}{3}\frac{1}{g^2} + \frac{1}{g_R^2}, \qquad \frac{1}{g_2^2} = \frac{1}{g_I^2}, \qquad \frac{1}{g_3^2} = \frac{1}{g^2},$$

**(3)** Vary  $m_R$  in a search for a unification scale  $\Lambda$  where

$$g_R = g_L = g$$

which is where the spectral action is valid as an effective theory.

# Phenomenology of the spectral Pati–Salam model Case I: Standard Model $\partial_F$

For the Standard Model Dirac operator, we have found that with  $m_R \approx 4.25 \times 10^{13} \text{ GeV}$  there is unification at  $\Lambda \approx 2.5 \times 10^{15} \text{ GeV}$ :

# Phenomenology of the spectral Pati–Salam model Case I: Standard Model $\partial_F$

In this case, we can also say something about the scalar particles that remain after SSB:

	$U(1)_Y$	$SU(2)_L$	<i>SU</i> (3)
$\begin{pmatrix} \phi_1^0 \\ \phi_1^+ \end{pmatrix} = \begin{pmatrix} \phi_1^1 \\ \phi_1^2 \end{pmatrix}$	1	2	1
$\begin{pmatrix} \phi_2^-\\ \phi_2^0\\ \phi_2^0 \end{pmatrix} = \begin{pmatrix} \phi_2^1\\ \phi_2^2\\ \phi_2^2 \end{pmatrix}$	-1	2	1
$\sigma$	0	1	1
$\eta$	$\left  -\frac{2}{3} \right $	1	3

- It turns out that these scalar fields have a little influence on the running of the SM-gauge couplings (at one loop).
- However, this sector contains the real scalar singlet  $\sigma$  that allowed for a realistic Higgs mass and that stabilizes the Higgs vacuum [CC 2012].

#### Phenomenology of the spectral Pati–Salam model Case II: General Dirac

For the more general case, we have found that with  $m_R \approx 1.5 \times 10^{11} \text{ GeV}$  there is unification at  $\Lambda \approx 6.3 \times 10^{16} \text{ GeV}$ :

With our walk through the noncommutative garden, we have arrived at a spectral Pati-Salam model that

- goes beyond the Standard Model
- has a fixed scalar sector once the finite Dirac operator has been fixed (only a few scenarios)
- exhibits grand unification for all of these scenarios (confirmed by [Aydemir–Minic–Sun–Takeuchi 2015])
- the scalar sector has the potential to stabilize the Higgs vacuum and allow for a realistic Higgs mass.
